

Session 2: Key-Value Stores (kompakt)

Lernziele: Key-Value Paradigma verstehen | Zugriffsmuster & Patterns kennen | Grenzen & Trade-offs bewerten

Rückblick: Was haben wir beim letzten Mal gelernt?

Willkommen zurück! Bevor wir in Key-Value Stores eintauchen, lasst uns kurz rekapitulieren, wo wir letzte Woche geendet haben.

Session 1 Recap

- ✓ **Rohdaten-Formate:** CSV, JSON, YAML, XML
- ✓ **Ad-hoc Analysen:** Programmiersprachen direkt auf CSV
- ✓ **Problem erkannt:** Lineare Suche = $O(n)O(n)$ Zeitkomplexität
- ✓ **Inkonsistenzen:** Keine Validierung, keine Integrität

Wir haben gesehen, dass Dateien flexibel sind, aber bei strukturierten Zugriffen schnell an Grenzen stoßen. Heute schauen wir uns an, wie Key-Value Stores dieses Problem lösen.

Zentrale Frage aus: Wie können wir schneller als $O(n)O(n)$ auf Daten zugreifen?

Wie dargestellt, benötigen wir linearen Zeitaufwand, um in eine Datei nach einem Eintrag zu suchen zu durchsuchen. Wenn ihr noch nicht wisst, was $O(n)O(n)$ bedeutet, keine Sorge – wir werden das gleich im Detail besprechen!

Das Problem: CSV-Suche ist langsam

Nehmen wir eine Produktdatenbank als Beispiel und schauen wir uns an, was passiert, wenn wir ein einzelnes Produkt suchen müssen.

Szenario: Wir haben eine CSV-Datei mit Produkten und wollen Details zu Produkt P00567 finden.

Eine typische Produkt-CSV mit ID, Name, Kategorie, Preis, Lagerbestand. Nichts Besonderes – aber schauen wir uns die Performance an!

Naive Implementierung: Lineare Suche

```

1  const response = await fetch("https://raw.githubusercontent.com/andre
    -dietrich/Datenbankensysteme-Vorlesung/refs/heads/main/assets/dat
    /products.csv");

```

```

2  const text = await response.text();
3  const rows = Papa.parse(text, { header: true }).data;
4
5  function searchProductById(productId) {
6      const start = performance.now();
7      let found = null;
8
9      // Zeilenweise durchsuchen (O(n)!)
10     for (let i = 0; i < rows.length; i++) {
11         sleep(1); // Simuliere Latenz (I/O, Parsing)
12         if (rows[i].product_id == productId) {
13             found = rows[i];
14             break;
15         }
16     }
17
18     const end = performance.now();
19
20     if (!found) {
21         console.log("❌ Produkt nicht gefunden");
22     } else {
23         console.log("✅ Produkt gefunden:", JSON.stringify(found, null, 2));
24     }
25
26     console.log("🕒 Zeit:", (end - start).toFixed(2), "ms");
27 }
28
29 searchProductById("P00567");

```

```

✅ Produkt gefunden: {
  "product_id": "P00567",
  "name": "Building Blocks Set Max",
  "category": "Toys",
  "brand": "SunnyPlay",
  "price": "46.45",
  "stock": "257",
  "rating": "4.7",
  "created_at": "2025-03-06"
}
🕒 Zeit: 566.70 ms

```

Probiert verschiedene Produkt-IDs aus! Beobachtet: Je weiter hinten das Produkt in der Datei steht, desto länger dauert die Suche. Im schlimmsten Fall müssen wir die gesamte Datei durchsuchen!

Problem: Lineare Suche = $O(n)$ **Zeitkomplexität**

- 1.000 Produkte? Noch ok (~1 Sekunde)
- 1.000.000 Produkte? **Nicht mehr praktikabel (~17 Minuten)**
- **Skalierungsproblem:** Verdoppelung der Daten = Verdoppelung der Suchzeit

Big-O Notation: Kurzer Exkurs

Big-O Notation ist eine mathematische Notation, die verwendet wird, um die Leistung oder Komplexität eines Algorithmus zu beschreiben. Sie konzentriert sich auf das Worst-Case-Szenario und ignoriert Konstanten und niedrigere Ordnungstermine. Aber was bedeutet das konkret?

Alltags-Analogie: Bücher im Regal finden

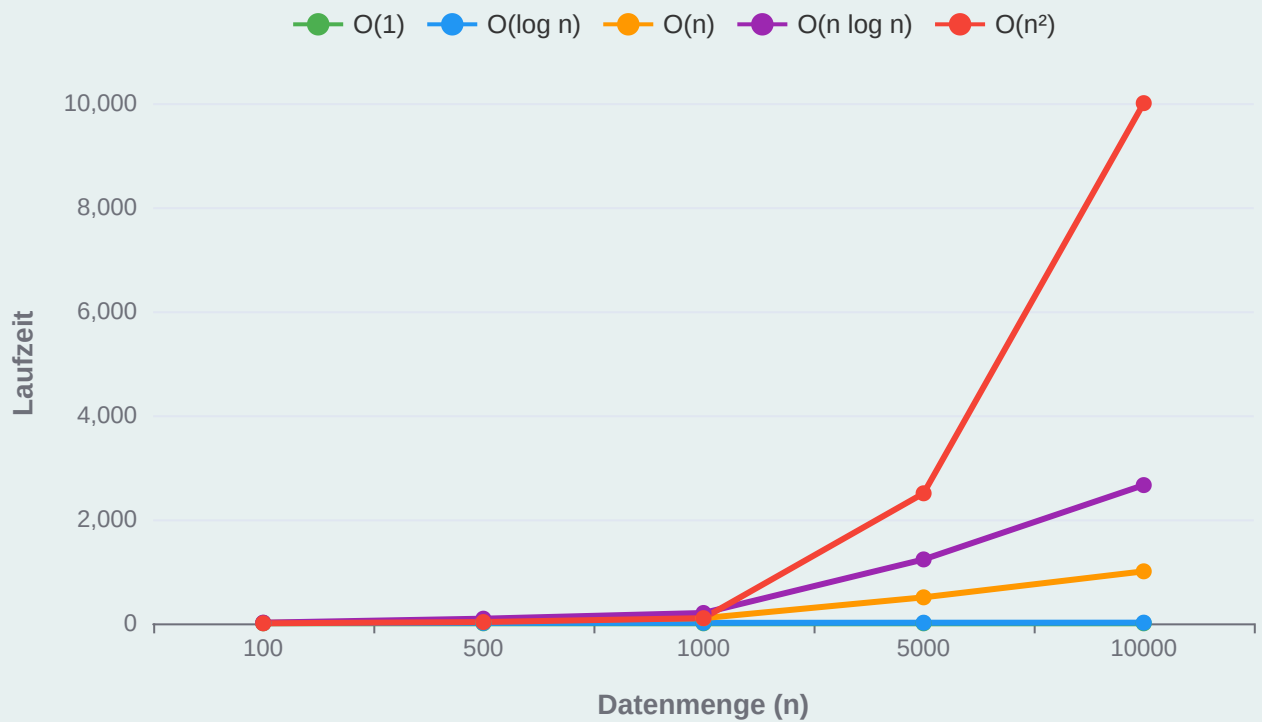

Stellt euch vor, ihr sucht ein bestimmtes Buch in einem Regal:

- $O(1)$ **Konstant:** Ihr wisst genau, wo das Buch steht (Position 42). Egal ob 10 oder 10.000 Bücher im Regal – ihr greift direkt zu. **Wie ein Hash-Lookup!**
- $O(\log n)$ **Logarithmisch:** Die Bücher sind alphabetisch sortiert. Ihr schaut in die Mitte, wisst ob links oder rechts, halbiert wieder – wie beim Telefonbuch. Bei 1.000 Büchern nur ~10 Schritte!
- $O(n)$ **Linear:** Bücher sind unsortiert. Ihr müsst jedes einzelne Buch durchgehen. 1.000 Bücher = 1.000 Checks im Worst Case. **Wie CSV-Scan!**
- $O(n \log n)$ **Linearithmisch:** Ihr wollt alle Bücher alphabetisch sortieren (z.B. mit MergeSort). Jedes Buch muss mindestens einmal angefasst werden (n), und dabei werden $\log n$ Vergleichsebenen durchlaufen. Langsamer als $O(n)$, aber viel schneller als $O(n^2)$!
- $O(n^2)$ **Quadratisch:** Ihr vergleicht jedes Buch mit jedem anderen (z.B. Duplikate finden). Bei 1.000 Büchern = 1.000.000 Vergleiche!

Diese Analogie macht klar: Die Wahl der richtigen Datenstruktur und des richtigen Algorithmus kann den Unterschied zwischen Millisekunden und Stunden ausmachen!

Visualisierung: Wachstum bei steigender Datenmenge

Big-O Komplexität: Laufzeit vs. Datenmenge

Seht ihr den Unterschied? $O(1)$ bleibt flach – egal wie viele Daten. $O(n^2)$ explodiert förmlich! Das ist der Grund, warum Hash-Tables so wertvoll sind. Bewegt die Maus über die Linien, um die genauen Werte zu sehen!

Die häufigsten Big-O-Klassen im Überblick

Komplexität	Name	Beispiel	100 Elemente	1.000 Elemente
$O(1)$ $O(1)$	Konstant	Hash-Lookup, Array[index]	1 ms	1 ms
$O(\log n)$ $O(\log n)$	Logarithmisch	Binäre Suche, Baum- Traversierung	~7 ms	~10 ms
$O(n)$ $O(n)$	Linear	Array durchsuchen, CSV scannen	100 ms	1 s
$O(n \log n)$ $O(n \log n)$	Linearithmisch	Gute Sortieralgorithmen (Mergesort)	~700 ms	~10 s
$O(n^2)$ $O(n^2)$	Quadratisch	Nested Loops, Bubble Sort	10 s	~17 min

Diese Tabelle zeigt: Ab einer bestimmten Datenmenge wird der Algorithmus zum Flaschenhals. $O(n^2)$ ist bei 1 Million Elementen praktisch unbenutzbar!

Konkrete Code-Beispiele

```
// O(1) - Konstant: Direkter Zugriff
const product = db["P00567"]; // Immer gleich schnell!

// O(n) - Linear: Alle Elemente durchgehen
for (let i = 0; i < products.length; i++) {
  if (products[i].id === "P00567") return products[i];
}

// O(log n) - Logarithmisch: Binäre Suche (nur bei sortierten Daten!)
function binarySearch(sortedArray, target) {
  let left = 0, right = sortedArray.length - 1;
  while (left <= right) {
    const mid = Math.floor((left + right) / 2);
    if (sortedArray[mid] === target) return mid;
    if (sortedArray[mid] < target) left = mid + 1;
    else right = mid - 1;
  }
  return -1;
}
```

```
// O(n²) - Quadratisch: Verschachtelte Loops
for (let i = 0; i < products.length; i++) {
  for (let j = 0; j < products.length; j++) {
    // Vergleiche jedes Produkt mit jedem anderen
  }
}
```

Der Code macht den Unterschied deutlich: Ein Hash-Lookup ist eine einzige Zeile. Eine verschachtelte Schleife muss potentiell Millionen von Operationen durchführen!

Merkregel: Je flacher die Kurve, desto besser skaliert der Algorithmus!

- **Gut:** $O(1)O(1)$, $O(\log n)O(\log n)$
- **Akzeptabel:** $O(n)O(n)$, $O(n \log n)O(n \log n)$
- **Problematisch:** $O(n^2)O(n^2)$, $O(2^n)O(2n)$, $O(n!)O(n!)$

Big-O Cheat Sheet: <https://www.bigocheatsheet.com/>

Die Lösung: Hash-basierter Index (Key-Value!)

Jetzt kommt der Aha-Moment: Was wäre, wenn wir die CSV einmal einlesen, aber dann einen Index bauen? Genau das macht ein Key-Value Store!

Optimierte Implementierung: Hash-Lookup

```
1  const response = await fetch("https://raw.githubusercontent.com/andre
   -dietrich/Datenbankensysteme-Vorlesung/refs/heads/main/assets/dat
   /products.csv");
2  const text = await response.text();
3  const rows = Papa.parse(text, { header: true }).data;
4
5  // Index bauen: Key = product_id, Value = komplettes Produkt-Objekt
6  const db = {};
7  rows.forEach((row) => {
8    db[row.product_id] = row;
9  });
10
11 function searchProductById(productId) {
12   const start = performance.now();
13
14   // O(1) Lookup! 🚀
15   sleep(1); // Simuliere minimale Latenz
16   const product = db[productId];
17
18   const end = performance.now();
19
20   if (product === undefined) {
```

```

20 if (product !== undefined) {
21   console.log("✅ Produkt gefunden:", JSON.stringify(product, null,
22 } else {
23   console.log("❌ Produkt nicht gefunden");
24 }
25
26 console.log("🕒 Zeit:", (end - start).toFixed(2), "ms");
27 }
28
29 searchProductById("P00567");

```

Identifier 'response' has already been declared

Boom! Von mehreren Sekunden auf unter 1 Millisekunde! Der Index macht den Unterschied: Wir zahlen einmal den Preis fürs Einlesen und Indexieren, danach sind alle Lookups blitzschnell.

Performance-Vergleich

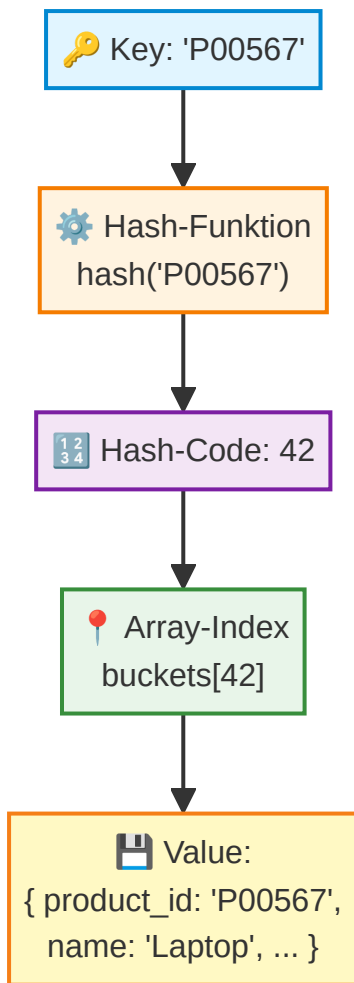

Methode	Zeitkomplexität	1.000 Produkte	1.000.000 Produkte
Lineare Suche	$O(n)$	1s	17min
Hash-Lookup	$O(1)$	< 1ms	< 1ms

Das ist die Superkraft von Key-Value: Konstante Zugriffszeit, egal wie viele Daten ihr habt!

Wie funktioniert das intern?

Aber wie kann ein Hash-basierter Index so schnell sein? Die Antwort: Hash-Funktionen! Schauen wir uns an, wie das im Detail funktioniert.

Das Prinzip: Von Key zu Array-Index

Eine Hash-Funktion nimmt einen beliebigen Key (String, Number) und berechnet daraus eine Zahl – den Hash-Code. Diese Zahl wird als Array-Index verwendet. Direkter Array-Zugriff ist $O(1)O(1)!$

Schritt-für-Schritt: Einfache Hash-Table Implementation

```
1 // Vereinfachte Hash-Table (zum Verständnis)
2 class SimpleHashTable {
3   constructor(size = 100) {
4     this.buckets = new Array(size); // Array mit 100 Slots
5     this.size = size;
6   }
7
8   // Hash-Funktion: String → Number
9   hash(key) {
10    let hashValue = 0;
11    for (let i = 0; i < key.length; i++) {
12      hashValue += key.charCodeAt(i); // ASCII-Wert summieren
13    }
14    return hashValue % this.size; // Modulo für Array-Größe
15  }
16
17  // SET: Key-Value speichern
18  set(key, value) {
```

```

19     const index = this.hash(key);
20     console.log(`SET "${key}" → Hash: ${index}`);
21     this.buckets[index] = { key, value }; // Vereinfacht!
22 }
23
24 // GET: Value abrufen
25 get(key) {
26     const index = this.hash(key);
27     console.log(`GET "${key}" → Hash: ${index}`);
28     const bucket = this.buckets[index];
29     return bucket ? bucket.value : undefined;
30 }
31 }
32
33 // Demo
34 const hashTable = new SimpleHashTable(10);
35
36 hashTable.set("P00567", { name: "Laptop", price: 999 });
37 hashTable.set("P00123", { name: "Mouse", price: 25 });
38 hashTable.set("P00999", { name: "Keyboard", price: 75 });
39
40 console.log("\n--- Lookups ---");
41 const laptop = hashTable.get("P00567");
42 console.log("Found:", laptop);
43
44 const mouse = hashTable.get("P00123");
45 console.log("Found:", mouse);
46
47 // Nicht vorhanden
48 const unknown = hashTable.get("P99999");
49 console.log("Found:", unknown);

```

```

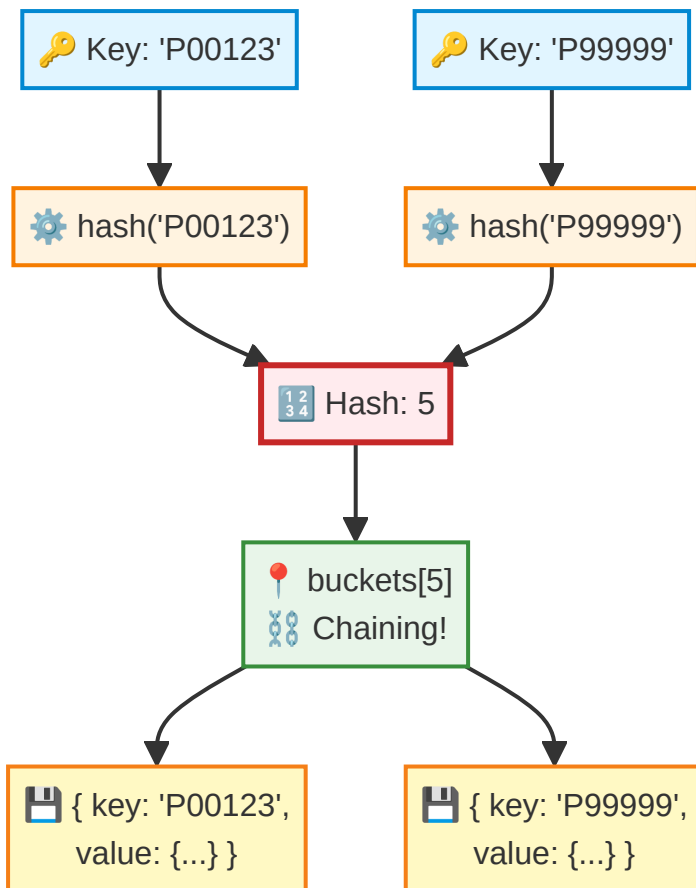

SET "P00567" → Hash: 8
SET "P00123" → Hash: 6
SET "P00999" → Hash: 7

--- Lookups ---
GET "P00567" → Hash: 8
Found: {"name":"Laptop","price":999}
GET "P00123" → Hash: 6
Found: {"name":"Mouse","price":25}
GET "P99999" → Hash: 5
Found: undefined

```

Seht ihr? Die Hash-Funktion berechnet aus dem Key einen Index. Dann greifen wir direkt auf `buckets[index]` zu – $O(1)$! Das ist die Magie hinter Hash-Tables.

Problem: Hash-Kollisionen

Hash-Kollisionen sind unvermeidbar! Die Lösung: Chaining. Jeder Bucket speichert eine Liste von Key-Value-Paaren. Bei einer Kollision durchsuchen wir nur diese kleine Liste – immer noch sehr schnell!

Verbesserte Implementation mit Collision-Handling

```

1 class HashTableWithChaining {
2   constructor(size = 10) {
3     this.buckets = new Array(size).fill(null).map(() => []);
4     this.size = size;
5   }
6
7   hash(key) {
8     let hashValue = 0;
9     for (let i = 0; i < key.length; i++) {
10      hashValue += key.charCodeAt(i);
11    }
12    return hashValue % this.size;
13  }
14
15  set(key, value) {
16    const index = this.hash(key);
17    const bucket = this.buckets[index];
18
19    // Prüfen ob Key schon existiert (Update)
20    for (let i = 0; i < bucket.length; i++) {
21      if (bucket[i].key === key) {

```

```

22     bucket[i].value = value;
23     console.log(`UPDATE "${key}" at bucket ${index}`);
24     return;
25 }
26 }
27
28 // Neuer Key → anhängen
29 bucket.push({ key, value });
30 console.log(`INSERT "${key}" at bucket ${index} (chain length: ${
    .length})`);
31 }
32
33 get(key) {
34     const index = this.hash(key);
35     const bucket = this.buckets[index];
36
37     // Bucket durchsuchen
38     for (let i = 0; i < bucket.length; i++) {
39         if (bucket[i].key === key) {
40             console.log(`FOUND "${key}" at bucket ${index}`);
41             return bucket[i].value;
42         }
43     }
44
45     console.log(`NOT FOUND "${key}"`);
46     return undefined;
47 }
48
49 // Debugging: Alle Buckets anzeigen
50 showBuckets() {
51     console.log("\n=== Hash Table Structure ===");
52     for (let i = 0; i < this.size; i++) {
53         if (this.buckets[i].length > 0) {
54             const keys = this.buckets[i].map(item => item.key).join(", ");
55             console.log(`Bucket ${i}: [${keys}]`);
56         }
57     }
58 }
59 }
60
61 // Demo mit Kollisionen
62 const ht = new HashTableWithChaining(5); // Kleiner = mehr Kollisionen
63
64 ht.set("P00123", { name: "Mouse", price: 25 });
65 ht.set("P00567", { name: "Laptop", price: 999 });
66 ht.set("P99999", { name: "Monitor", price: 299 });
67 ht.set("P00321", { name: "Keyboard", price: 75 });
68
69 ht.showBuckets();
70
71 console.log("\n=== Looking up ===");

```

```

71 console.log( \n--- Lookups --- ),
72 console.log("Mouse:", ht.get("P00123"));
73 console.log("Laptop:", ht.get("P00567"));
74 console.log("Unknown:", ht.get("XXXXX"));

```

```

INSERT "P00123" at bucket 1 (chain length: 1)
INSERT "P00567" at bucket 3 (chain length: 1)
INSERT "P99999" at bucket 0 (chain length: 1)
INSERT "P00321" at bucket 1 (chain length: 2)

```

=== Hash Table Structure ===

```

Bucket 0: [P99999]
Bucket 1: [P00123, P00321]
Bucket 3: [P00567]

```

--- Lookups ---

```

FOUND "P00123" at bucket 1
Mouse: {"name":"Mouse","price":25}
FOUND "P00567" at bucket 3
Laptop: {"name":"Laptop","price":999}
NOT FOUND "XXXXX"
Unknown: undefined

```

Diese Implementation zeigt: Selbst mit Kollisionen ist der Lookup extrem schnell! Solange die Bucket-Listen kurz bleiben (gute Hash-Funktion + ausreichende Größe), haben wir praktisch $O(1)O(1)$.

In der Praxis: JavaScript-Objekte, Redis, Python Dictionaries – alle nutzen Hash-Tables mit ausgeklügelten Hash-Funktionen und automatischer Größenanpassung (Rehashing).

Grenzen von Key-Value Stores

Jetzt kommt der Haken: Key-Value ist perfekt für ID-Lookups, aber was ist mit komplexeren Abfragen?

Szenario: Finde alle Produkte mit Lagerbestand < 10 (Low Stock Alert)

```

1 function filterProductsBy(filter) {
2   const start = performance.now();
3   const results = [];
4
5   // Müssen ALLE Keys durchsuchen! (wieder O(n))
6   for (const productId in db) {
7     sleep(1); // Simuliere Latenz
8     const product = db[productId];
9     if (filter(product)) {
10      results.push(product);
11    }

```

```
12 }
13
14 const end = performance.now();
15
16 if (results.length > 0) {
17     console.log("✅ Produkte gefunden:", JSON.stringify(results, null, 2));
18 } else {
19     console.log("❌ Keine Produkte gefunden");
20 }
21
22 console.log("🕒 Zeit:", (end - start).toFixed(2), "ms");
23 }
24
25 filterProductsBy(p => parseInt(p.stock) < 10);
```

```

Und schon sind wir wieder bei $O(n)O(n)$! Key-Value ist fantastisch für exakte ID-Lookups, aber für Range-Queries oder Filter brauchen wir andere Paradigmen. Das ist der Trade-off!

Key Insight: Key-Value ist kein Allheilmittel – es ist ein Werkzeug für einen spezifischen Use Case: schneller Key-basierter Zugriff.

Das Key-Value Prinzip: Formalisiert

Gut! Wir haben gesehen, dass Hash-basierte Indizes blitzschnell sind. Jetzt formalisieren wir das Ganze: Was genau ist ein Key-Value Store?

Definition

Ein Key-Value Store ist eine Datenstruktur, die:

- **Keys** (eindeutige Identifikatoren, meist Strings) auf **Values** (beliebige Daten) abbildet
- **$O(1)$ Lookup** garantiert (durchschnittlicher Fall)
- **Keine Struktur** für Values vorgibt (Blobs, JSON, Strings, ...)
- **Kein Schema** erzwingt

Heute schauen wir uns an, wie professionelle Key-Value Stores wie Redis diese Prinzipien umsetzen – und welche zusätzlichen Features sie bieten.

Historische Entwicklung der Key-Value Stores

Bevor wir die technischen Details betrachten, lohnt sich ein Blick in die Geschichte: Wie entstand das Key-Value-Prinzip und warum ist es heute so wichtig?

Frühe Anfänge

- Schon in den 1960er/70er Jahren tauchten assoziative Arrays in Sprachen wie Lisp und Perl auf.
- Betriebssysteme nutzten Key-Value-Konzepte für Konfigurationsdateien und Registries.

Die Idee, Daten über eindeutige Schlüssel blitzschnell zu finden, ist also älter als die meisten modernen Datenbanksysteme.

Erste Datenbanksysteme & Web-Ära

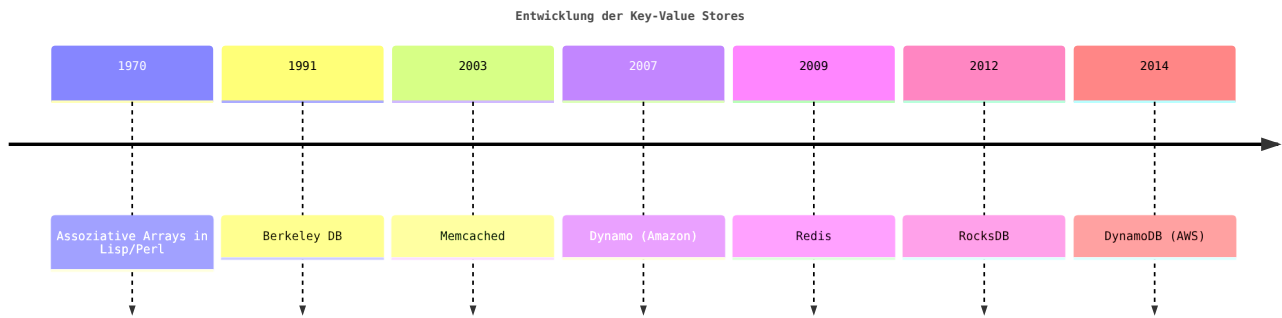

- Mit Berkeley DB und später Memcached (Ende 1990er/2000er) wurde das Prinzip für Performance und horizontale Skalierung genutzt.
- Die Web-Ära brachte neue Herausforderungen: Millionen von Nutzern, Sessions, Caching – Key-Value Stores wurden zum Rückgrat vieler Webanwendungen.

Das CAP-Theorem (Consistency, Availability, Partition Tolerance) trieb die Entwicklung von verteilten Key-Value Stores wie DynamoDB und Redis voran.

Moderne Key-Value Stores

- Heute sind Redis, DynamoDB, RocksDB und LevelDB die Platzhirsche.
- Features wie TTL, atomare Operationen, Replikation und Sharding machen sie unverzichtbar für Cloud, Microservices und Echtzeit-Anwendungen.

Key-Value Stores sind nicht nur schnell, sondern auch extrem flexibel und skalierbar.

Der Zeitstrahl zeigt: Die Entwicklung verlief parallel zu den Anforderungen an Skalierbarkeit und Performance im Web.

Visualisierung: Key → Value Mapping

Das Grundprinzip ist denkbar einfach: Jeder Wert wird über einen eindeutigen Schlüssel gespeichert und abgerufen. Kein Schema, keine Tabellen, keine Joins – nur Schlüssel und Werte.

Key-Value Store	
'user:42'	→ { name: 'Alice' , . . . }
'session:xyz'	→ { expires: 17000000000 }
'counter:views'	→ 12345

Der Clou: Der Zugriff erfolgt in konstanter Zeit – O von 1. Egal ob ihr 100 oder 100 Millionen Keys habt, der Lookup ist gleich schnell. Das ist die Superkraft von Key-Value Stores.

Grundoperationen

Operation	Beschreibung	Beispiel
SET	Wert speichern	SET user:42 '{"name":"Alice"}'
GET	Wert abrufen	GET user:42
DELETE	Wert löschen	DELETE user:42
EXISTS	Prüfen ob Key existiert	EXISTS user:42

Diese vier Operationen sind das Rückgrat jedes Key-Value Stores. Simpel, aber mächtig.

Redis in Action

Schauen wir uns das Ganze in Aktion an. Ich zeige euch echte Redis-Operationen, die ihr direkt im Browser ausführen könnt – ohne Server-Setup!

Redis Basics: SET & GET

```
1  const redis = new Redis();
2
3  // User-Daten speichern
4  await redis.set('user:42', JSON.stringify({
5    name: "Alice",
6    email: "alice@example.org"
7  }));
8
9  // Daten abrufen
10 const userData = await redis.get('user:42');
11 const user = JSON.parse(userData);
12
13 console.log('User Name:', user.name);
14 console.log('User Email:', user.email);
15
16 // Atomic Counter
17 await redis.set('page:views', '0');
18 await redis.incr('page:views');
19 await redis.incr('page:views');
20 await redis.incr('page:views');
21
22 const views = await redis.get('page:views');
23 console.log('Page Views:', views);
```

```
User Name: Alice
User Email: alice@example.org
Page Views: 3
```

Redis ist der Klassiker: In-Memory, blitzschnell, mit optionaler Persistierung. Perfekt für Caching, Session Stores, Leaderboards. Hier läuft es direkt im Browser – probiert es aus!

Hash Operations: Strukturierte Objekte

```
1  const redis = new Redis();
2
3  // User als Hash speichern (effizienter!)
4  await redis.hset('user:1001', 'name', 'Bob');
5  await redis.hset('user:1001', 'email', 'bob@example.org');
6  await redis.hset('user:1001', 'age', '28');
7  await redis.hset('user:1001', 'role', 'developer');
```

```

8
9 // Gesamtes Hash abrufen
10 const user = await redis.hgetall('user:1001');
11 console.log('User Object:', user);
12
13 // Einzelnes Feld abrufen
14 const name = await redis.hget('user:1001', 'name');
15 console.log('Name:', name);
16
17 // Feld existiert?
18 const hasPhone = await redis.hexists('user:1001', 'phone');
19 console.log('Has Phone:', hasPhone === 1);

```

User Object:

```
{ "name": "Bob", "email": "bob@example.org", "age": "28", "role": "developer" }
```

Name: Bob

Has Phone: false

Redis Hashes sind effizienter als JSON-Strings, wenn ihr nur einzelne Felder abrufen oder ändern wollt. Jedes Feld ist separat zugreifbar – perfekt für User-Profile!

TTL & Expiration: Selbstlöschende Daten

Eine der Killer-Features von Key-Value Stores: Time-To-Live oder TTL. Keys können automatisch ablaufen – perfekt für Sessions, Caches, Rate Limiting.

TTL in Action

```

1 const redis = new Redis();
2
3 // Session mit 10 Sekunden TTL
4 await redis.set('session:abc', JSON.stringify({ user_id: 42 }), 'EX',
5
6 // TTL abfragen
7 let ttl1 = await redis.ttl('session:abc');
8 console.log('TTL session:abc:', ttl1, 'seconds');
9
10 // Alternative: TTL nachträglich setzen
11 await redis.set('cache:data', 'cached_value');
12 await redis.expire('cache:data', 30);
13
14 let ttl2 = await redis.ttl('cache:data');
15 console.log('TTL cache:data:', ttl2, 'seconds');
16
17 // Key existiert?
18 const exists = await redis.exists('session:abc');
19 console.log('Session exists:', exists === 1);

```

```
TTL session:abc: 10 seconds
TTL cache:data: 30 seconds
Session exists: true
```

Nach Ablauf der Zeit ist der Key einfach weg. Keine manuellen Cleanup-Jobs nötig – der Store kümmert sich selbst darum. In diesem Beispiel seht ihr, wie TTL funktioniert.

Use Case: Session Store – nach 1 Stunde Inaktivität wird die Session automatisch gelöscht. Perfekt für Web-Apps!

Atomic Operations: Race Conditions vermeiden

Jetzt wird's interessant: Was passiert, wenn zwei Prozesse gleichzeitig denselben Counter hochzählen wollen?

Das Problem: Lost Update

```
1 // Simulation: Zwei "Prozesse" versuchen gleichzeitig zu inkrementieren
2 const redis = new Redis();
3 await redis.set('counter', '10');
4
5 // Naiver Ansatz (UNSICHER!)
6 async function unsafeIncrement(processId) {
7   const value = parseInt(await redis.get('counter'));
8   const newValue = value + 1;
9   await redis.set('counter', newValue.toString());
10
11   console.debug(`Process ${processId} increments counter to:`, newValue);
12
13   return newValue;
14 }
15
16 // Beide "Prozesse" lesen denselben Wert (10)
17 console.log('Process 1 reads:', await redis.get('counter'));
18 console.log('Process 2 reads:', await redis.get('counter'));
19
20 // Beide schreiben 11 – ein Update geht verloren!
21 await Promise.all([unsafeIncrement(1), unsafeIncrement(2)]);
22
23 const final = await redis.get('counter');
24 console.log('Final value:', final, '(should be 12, but is 11!');
```

```
Process 1 reads: 10
Process 2 reads: 10
Process 1 increments counter to: 11
Process 2 increments counter to: 11
Final value: 11 (should be 12, but is 11!)
```

Das ist eine klassische Race Condition: Beide lesen denselben Wert, beide schreiben denselben Wert plus 1 – ein Inkrement geht verloren. Lost Update!

Die Lösung: Atomic INCR

```
1  const redis = new Redis();
2  await redis.set('counter', '10');
3
4  // Atomares Inkrementieren (SICHER!)
5  const result1 = await redis.incr('counter');
6  console.log('After INCR #1:', result1);
7
8  const result2 = await redis.incr('counter');
9  console.log('After INCR #2:', result2);
10
11 const result3 = await redis.incr('counter');
12 console.log('After INCR #3:', result3);
13
14 // Auch mit INCRBY
15 await redis.incrby('counter', 5);
16 const final = await redis.get('counter');
17 console.log('After INCRBY 5:', final);
```

```
After INCR #1: 11
After INCR #2: 12
After INCR #3: 13
After INCRBY 5: 18
```

Redis garantiert: INCR ist atomar. Mehrere Prozesse können parallel inkrementieren, ohne dass Updates verloren gehen. Das ist die Magie atomarer Operationen!

Weitere atomare Operationen

Operation	Beschreibung
<code>INCR</code>	Atomares Inkrementieren um 1
<code>DECR</code>	Atomares Dekrementieren um 1
<code>INCRBY n</code>	Atomares Addieren von n
<code>DECRBY n</code>	Atomares Subtrahieren von n
<code>GETSET</code>	Setzen und alten Wert zurückgeben (atomar)
<code>SETNX</code>	Set if Not eXists (für Locking/Semaphoren)

Diese Operationen sind eure Waffen gegen Race Conditions. Nutzt sie!

Key-Design Patterns: Organisation ist alles

Keys sind nur Strings – aber wie organisiert man tausende oder Millionen Keys sinnvoll? Hier kommen Key-Design Patterns ins Spiel.

Pattern 1: Namespacing

```
user:42:profile
user:42:settings
user:42:sessions

product:99:details
product:99:reviews
product:99:inventory
```

Mit Doppelpunkten strukturieren wir Keys hierarchisch. Das ist nur eine Konvention, aber sie macht Keys lesbar und wartbar.

Pattern 2: Composite Keys

```
session:{user_id}:{timestamp}
cart:{session_id}:{product_id}
rate_limit:{ip}:{endpoint}:{minute}
```

Mehrere Dimensionen in einem Key – perfekt für komplexere Zugriffsszenarien.

Pattern 3: Leaderboard mit Sorted Sets

```
1 const redis = new Redis();
2
```

```

3 // Gaming Leaderboard erstellen
4 await redis.zadd('leaderboard', 9500, 'player:alice');
5 await redis.zadd('leaderboard', 8200, 'player:bob');
6 await redis.zadd('leaderboard', 12000, 'player:charlie');
7 await redis.zadd('leaderboard', 7800, 'player:diana');
8 await redis.zadd('leaderboard', 10500, 'player:eve');
9
10 // Top 3 Spieler (absteigend sortiert)
11 let topPlayers = await redis.zrevrange('leaderboard', 0, 2, 'WITHSCORES');
12 console.log('🏆 Top 3 Players:');
13 for (let i = 0; i < topPlayers.length; i += 2) {
14     const rank = i / 2 + 1;
15     const player = topPlayers[i];
16     const score = topPlayers[i + 1];
17     console.log(`  ${rank}. ${player} - ${score} points`);
18 }
19
20 // Rang eines bestimmten Spielers
21 const aliceRank = await redis.zrevrank('leaderboard', 'player:alice');
22 console.log(`\nAlice's Rank: #${aliceRank + 1}`);
23
24 // Score erhöhen (atomar!)
25 await redis.zincrby('leaderboard', 500, 'player:alice');
26 const newScore = await redis.zscore('leaderboard', 'player:alice');
27 console.log(`Alice's new score: ${newScore}`);

```

```

🏆 Top 3 Players:
1. player:charlie - 12000 points
2. player:eve - 10500 points
3. player:alice - 9500 points

```

```

Alice's Rank: #3
Alice's new score: 10000

```

Redis Sorted Sets sind perfekt für Ranglisten, Top-N Queries, Zeitreihen. Jedes Element hat einen Score, die Sortierung erfolgt automatisch. Ideal für Gaming, Analytics, Trending Topics!

Typische Use Cases

Wo KV glänzt

Jetzt wissen wir, WIE Key-Value funktioniert. Aber WANN sollten wir es einsetzen?

Use Case Matrix

Use Case	Warum KV?	Beispiel
Caching	$O(1)O(1)$ Lookup, TTL	Seiten-Cache, API-Responses
Session Store	Schneller Zugriff, Expiration	User Sessions, JWT
Rate Limiting	Atomic Counters, TTL	API Rate Limits (pro Minute)
Leaderboards	Sorted Sets	Gaming, Analytics
Feature Flags	Schneller Read, einfaches Update	A/B Tests, Rollouts

Überall dort, wo ihr schnellen Key-basierten Zugriff braucht und keine komplexen Queries, ist Key-Value ideal.

Referenzen

- Caching Strategies: [Cache Stampede Problem](#)
- Rate Limiting: [Token Bucket Algorithm](#)

Grenzen: Was KV NICHT kann

Kein Paradigma ist perfekt. Schauen wir uns an, wo Key-Value an seine Grenzen stößt.

Problem 1: Keine Range Queries

```
// Ich will alle User mit IDs zwischen 100 und 200
// ✗ Nicht möglich mit Standard Key-Value!

// Workaround: Alle Keys durchsuchen (teuer!)
KEYS user:*
```

Key-Value kennt nur exakte Lookups. Bereichsabfragen? Fehlanzeige. Dafür bräuchten wir Indexstrukturen – die hat KV nicht.

Problem 2: Keine Joins

```
// Ich will alle Bestellungen eines Users UND die Produktdetails
// ✗ Keine Joins in KV!

// Workaround: Mehrere GET Requests
GET user:42:orders // → [99, 100, 101]
GET product:99
GET product:100
GET product:101
```

Jede Relation muss manuell aufgelöst werden. Bei komplexen Datenmodellen wird das schnell unübersichtlich.

Problem 3: Keine Ad-hoc Analysen

```
// "Zeige alle User, die in den letzten 7 Tagen aktiv waren"
// ✗ Ohne Secondary Indexes nicht möglich
```

Analytische Abfragen erfordern Strukturinformationen, die Key-Value nicht hat. Dafür brauchen wir Document, Column oder Relational Stores.

Trade-off: KV ist simpel und schnell, aber unflexibel. Für komplexe Queries brauchen wir reichhaltigere Paradigmen.

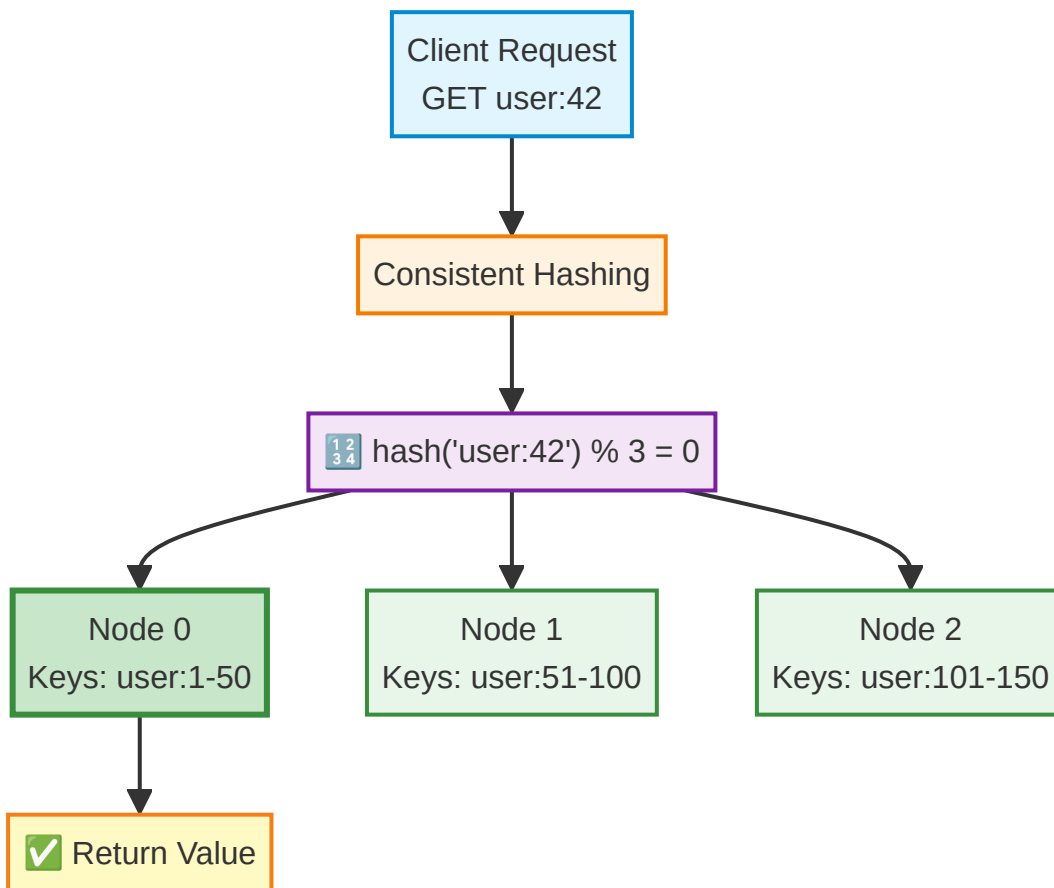

Parallelisierung und Skalierung

Ein letzter Punkt: Wie skaliert Key-Value, wenn die Datenmengen wachsen? Key-Value Stores haben hier einen entscheidenden Vorteil: Sie sind von Natur aus horizontal skalierbar.

Sharding: Daten auf mehrere Knoten verteilen

Sharding bedeutet, dass wir unsere Keys auf mehrere Nodes verteilen. Jeder Node ist für einen bestimmten Key-Bereich verantwortlich.

Visualisierung: Hash-based Sharding

Mit Consistent Hashing berechnen wir aus jedem Key, auf welchem Node die Daten liegen. Das ermöglicht horizontale Skalierung: Mehr Nodes = mehr Kapazität!

Beispiel: Sharding in der Praxis

```
1 // Simulation eines einfachen Sharding-Clients
2 class ShardedKeyValueClient {
3   constructor(nodes) {
4     this.nodes = nodes; // Array von Node-IDs
5   }
6
7   // Consistent Hashing: Key → Node
8   getNodeForKey(key) {
9     let hash = 0;
10    for (let i = 0; i < key.length; i++) {
11      hash += key.charCodeAt(i);
12    }
13    const nodeIndex = hash % this.nodes.length;
14    return this.nodes[nodeIndex];
15  }
16 }
```

```

15     }
16
17     // GET: Ermittle Node und hole Wert
18     get(key) {
19         const node = this.getNodeForKey(key);
20         console.log(`GET "${key}" → routed to ${node}`);
21         // In der Realität: HTTP Request an den Node
22         return `[Value from ${node}]`;
23     }
24
25     // SET: Ermittle Node und speichere Wert
26     set(key, value) {
27         const node = this.getNodeForKey(key);
28         console.log(`SET "${key}" → routed to ${node}`);
29         // In der Realität: HTTP Request an den Node
30         return `OK (stored on ${node})`;
31     }
32 }
33
34 // Demo: 3 Nodes
35 const client = new ShardedKeyValueClient(['node-0', 'node-1', 'node-2']
36
37 console.log('=== Sharding Demo ===\n');
38
39 // Verschiedene Keys werden auf unterschiedliche Nodes verteilt
40 client.set('user:42', '{"name":"Alice"}');
41 client.set('user:99', '{"name":"Bob"}');
42 client.set('product:123', '{"name":"Laptop"}');
43 client.set('session:abc', '{"user_id":42}');
44 client.set('cart:xyz', '{"items":[1,2,3]}');
45
46 console.log('\n--- Retrieving Data ---\n');
47
48 client.get('user:42');
49 client.get('product:123');
50 client.get('session:abc');
51
52 console.log('\n💡 Jeder Key landet auf einem bestimmten Node!');
53 console.log('    → Mehr Nodes = mehr Parallelität und Kapazität');

```

```
=== Sharding Demo ===
```

```
SET "user:42" → routed to node-1  
SET "user:99" → routed to node-1  
SET "product:123" → routed to node-2  
SET "session:abc" → routed to node-2  
SET "cart:xyz" → routed to node-1
```

```
--- Retrieving Data ---
```

```
GET "user:42" → routed to node-1  
GET "product:123" → routed to node-2  
GET "session:abc" → routed to node-2
```

Jeder Key landet auf einem bestimmten Node!

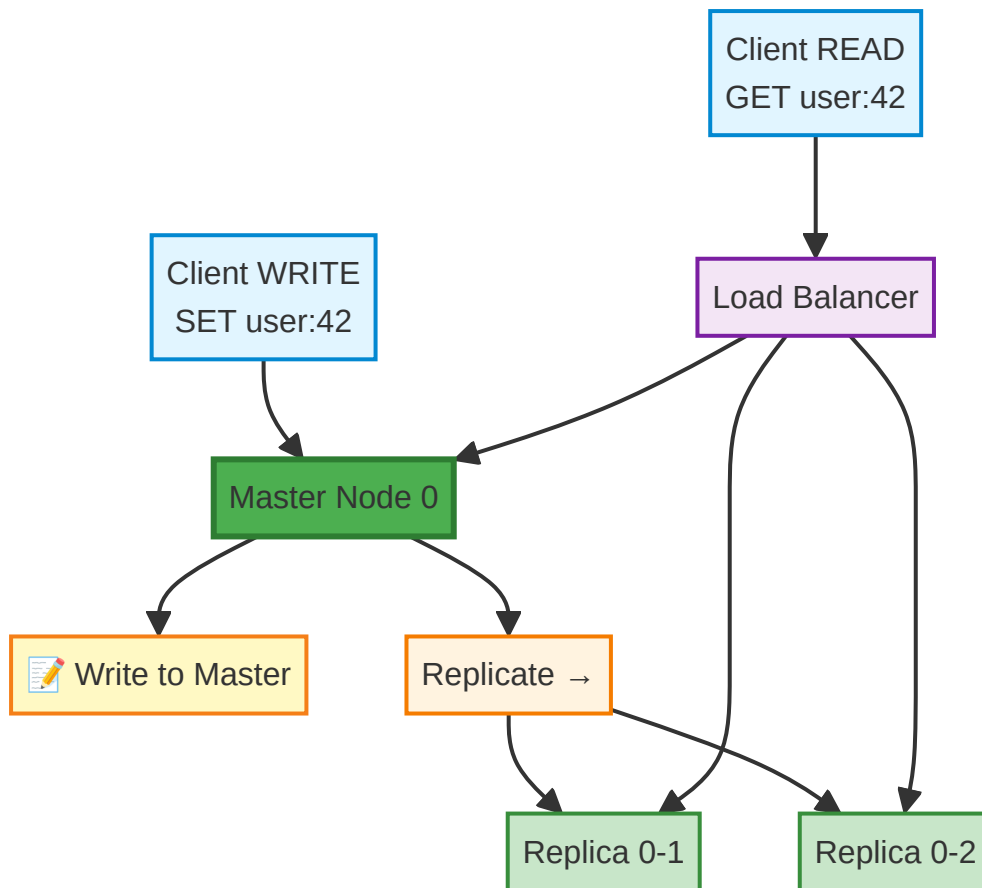

→ Mehr Nodes = mehr Parallelität und Kapazität

Seht ihr? Jeder Key wird automatisch einem Node zugeordnet. Das System skaliert linear: 3 Nodes können 3x so viele Requests parallel verarbeiten wie 1 Node!

Replication: Ausfallsicherheit durch Redundanz

Sharding allein reicht nicht – was passiert, wenn ein Node ausfällt? Hier kommt Replication ins Spiel.

Master-Replica Architektur

Schreiboperationen gehen an den Master, der dann asynchron an Replicas repliziert. Lesezugriffe können vom Master oder von beliebigen Replicas bedient werden – das verteilt die Last!

Trade-offs bei Replication

Replikations-Typ	Konsistenz	Performance	Use Case
Synchron	✓ Stark	⚠ Langsam	Finanztransaktionen
Asynchron	⚠ Eventual	✓ Schnell	Social Media Feeds, Caching
Semi-Synchron	● Mittel	● Mittel	E-Commerce, Session Stores

Der Klassiker: Konsistenz vs. Performance. Für Session Stores ist Eventual Consistency meist ok – für Banküberweisungen nicht!

Redis Enterprise & CRDTs

Jetzt wird's spannend: Redis Enterprise nutzt **CRDTs** (Conflict-free Replicated Data Types) für Multi-Master-Replication ohne Konflikte!

Was sind CRDTs?

CRDTs sind Datenstrukturen, die **garantiert konfliktfrei** zusammengeführt werden können, selbst wenn mehrere Replicas gleichzeitig Updates erhalten.

Beispiel: Counter-CRDT

```
1 // Klassisches Problem: Zwei Replicas inkrementieren gleichzeitig
2 // Replica 1: counter = 10 → 11
3 // Replica 2: counter = 10 → 11
4 // Merge: Was ist das Ergebnis? 11? 12? ❌ Konflikt!
5
6 // CRDT-Lösung: G-Counter (Grow-only Counter)
7 class GCounter {
8   constructor(replicaId) {
9     this.replicaId = replicaId;
10    this.counters = {}; // Pro Replica ein eigener Counter
11  }
12
13  increment() {
14    if (!this.counters[this.replicaId]) {
15      this.counters[this.replicaId] = 0;
16    }
17    this.counters[this.replicaId]++;
18    console.log(`Replica ${this.replicaId}: local counter = ${this
19      .counters[this.replicaId]}`);
20  }
21  value() {
22    // Gesamtwert: Summe aller Replica-Counter
23    return Object.values(this.counters).reduce((sum, val) => sum + val, 0);
24  }
25
26  merge(other) {
27    // Merge: Maximum pro Replica nehmen
28    for (const [replica, count] of Object.entries(other.counters)) {
29      if (!this.counters[replica] || this.counters[replica] < count) {
30        this.counters[replica] = count;
31      }
32    }
33    console.log(`Merged: total = ${this.value()}`);
34  }
35 }
36
37 // Simulation: Zwei Replicas inkrementieren unabhängig
38 console.log('=== CRDT Counter Demo ===\n');
39
40 const replica1 = new GCounter('replica-1');
41 const replica2 = new GCounter('replica-2');
42
43 replica1.increment(); // replica-1: 1
44 replica1.increment(); // replica-1: 2
45
```

```

46 replica2.increment(); // replica-2: 1
47 replica2.increment(); // replica-2: 2
48 replica2.increment(); // replica-2: 3
49
50 console.log('\nBefore merge:');
51 console.log(`  Replica 1 sees: ${replica1.value()}`);
52 console.log(`  Replica 2 sees: ${replica2.value()}`);
53
54 console.log('\nMerging Replica 2 → Replica 1:');
55 replica1.merge(replica2);
56
57 console.log('\nAfter merge:');
58 console.log(`  Total: ${replica1.value()} ✅ (2 + 3 = 5, kein Verlust

```

=== CRDT Counter Demo ===

```

Replica replica-1: local counter = 1
Replica replica-1: local counter = 2
Replica replica-2: local counter = 1
Replica replica-2: local counter = 2
Replica replica-2: local counter = 3

```

Before merge:

```

  Replica 1 sees: 2
  Replica 2 sees: 3

```

Merging Replica 2 → Replica 1:

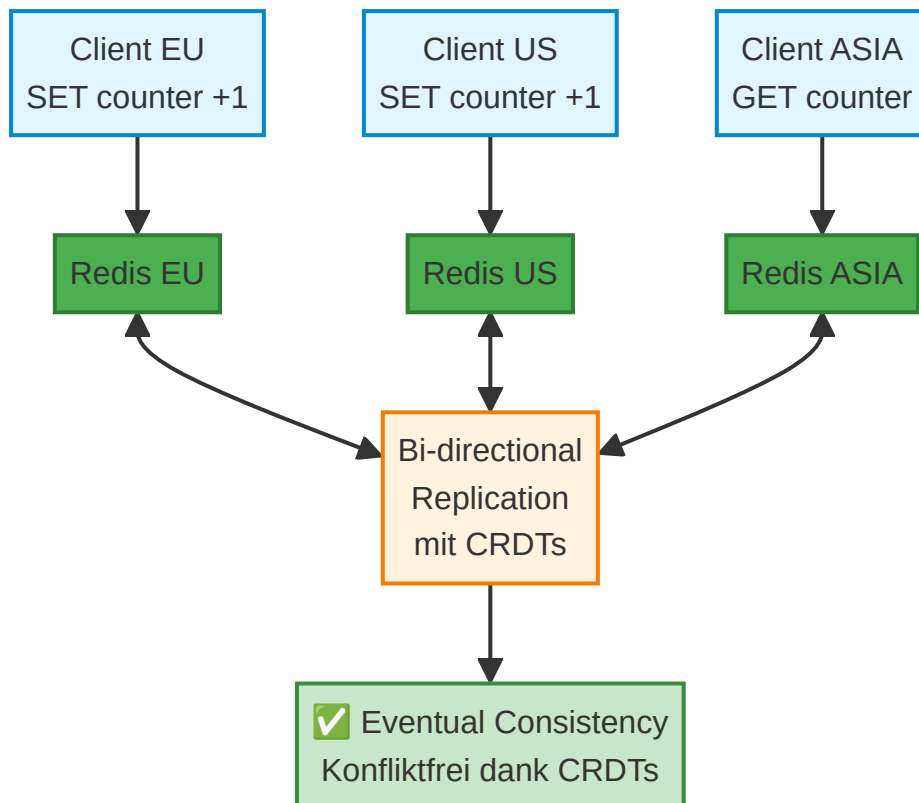

Merged: total = 5

After merge:

Total: 5 ✅ (2 + 3 = 5, kein Verlust!)

CRDTs lösen das Problem mathematisch: Jede Replica hat ihren eigenen Counter. Beim Merge nehmen wir das Maximum – garantiert konfliktfrei! Redis Enterprise nutzt dies für Active-Active Geo-Replication.

Redis Enterprise: Active-Active mit CRDTs

Mit Redis Enterprise könnt ihr weltweit verteilte Master-Nodes haben, die alle Writes akzeptieren. CRDTs garantieren, dass alle Replicas konfliktfrei konvergieren – ohne manuelle Konfliktauflösung!

CRDT-Typen in Redis Enterprise

CRDT-Typ	Operationen	Use Case
Counter	INCR, DECR	Page Views, Likes
Register	SET (Last-Write-Wins)	User Status, Config
Set	SADD, SREM	Tags, Permissions
Sorted Set	ZADD (max score wins)	Leaderboards
Hash	HSET (per-field LWW)	User Profiles

Redis Enterprise unterstützt verschiedene CRDT-Typen out-of-the-box. Ihr schreibt normalen Redis-Code, das System kümmert sich um Konfliktauflösung!

Herausforderungen bei Skalierung

Trotz aller Vorteile gibt es Herausforderungen:

Die Realität

- **Konsistenz:** Bei verteilten Systemen schwieriger zu gewährleisten
 - CAP-Theorem: Consistency, Availability, Partition Tolerance – pick two!
 - Eventual Consistency ist oft ein Kompromiss
- **Netzwerk-Latenz:** Mehr Nodes = mehr Kommunikation
 - Cross-Region Replication: 100+ ms Latenz
 - Lösung: Geo-Partitioning, lokale Caches
- **Rebalancing:** Bei Änderungen in der Datenverteilung aufwendig
 - Neuer Node hinzufügen? → Keys müssen umverteilt werden
 - Consistent Hashing minimiert Umverteilung (nur $\sim 1/n$ der Keys bewegen sich)

Verteilte Systeme sind komplex! Redis Enterprise und ähnliche Lösungen nehmen euch viel Arbeit ab, aber das Verständnis der Trade-offs bleibt essentiell.

Best Practice: Startet einfach (Single Node), skaliert bei Bedarf horizontal. Premature Optimization ist die Wurzel allen Übels!

Zusammenfassung & Wrap-up

Fassen wir zusammen: Key-Value Stores sind das Schweizer Taschenmesser für schnelle, strukturierte Zugriffe. Simpel, robust, blitzschnell.

Key Takeaways

-  **O(1) Lookup:** Konstante Zugriffszeit, egal bei welcher Datenmenge
-  **TTL & Expiration:** Selbstlöschende Daten für Sessions, Caches
-  **Atomare Operationen:** Race Conditions vermeiden mit `INCR`, `SETNX`
-  **Key-Design Patterns:** Namespacing, Composite Keys, Sorted Sets
-  **Replikation:** Daten werden auf mehrere Knoten verteilt (Master-Replica, semi-synchron, asynchron) für Ausfallsicherheit und Skalierung
-  **Partitionierung (Sharding):** Daten werden logisch oder technisch aufgeteilt, um große Datenmengen und viele Zugriffe zu bewältigen
-  **Konsistenzmodelle:** Von starker Konsistenz (alle sehen immer den aktuellen Stand) bis zu eventual consistency (Daten gleichen sich zeitverzögert ab)
-  **Keine Range Queries:** Nur exakte Lookups möglich
-  **Keine Joins:** Relationen manuell auflösen
-  **Keine Ad-hoc Analysen:** Strukturinformationen fehlen

Key-Value ist perfekt für Caching, Sessions, Rate Limiting – überall dort, wo Geschwindigkeit und Einfachheit zählen. Für komplexere Datenmodelle schauen wir uns in den nächsten Sessions Document und Column Stores an.

Interaktives Redis-Terminal

```

1 // Redis Playground: Experimentiert selbst!
2 redis = new Redis();
3
4 // Initial Setup
 5 await redis.set('counter', '0');
 6 await redis.hset('user:demo', 'name', 'Demo User');
 7 await redis.zadd('scores', 100, 'Alice');
8
9 console.log('🎮 Redis Playground Ready!\n');
10 console.log('Try these commands:');
11 console.log('  await redis.incr("counter");');
12 console.log('  await redis.get("counter");');
13 console.log('  await redis.hgetall("user:demo");');
14 console.log('  await redis.zadd("scores", 200, "Bob");');
15 console.log('  await redis.zrevrange("scores", 0, -1, "WITHSCORES");');
16 console.log('  await redis.keys("*");');

```

Nutzt das Terminal, um selbst zu experimentieren! Probiert verschiedene Befehle aus, baut eigene Use Cases – Learning by Doing!
